

CrossCredit

Cross-chain credit reputation and lending on Creditcoin,
priced on *proof* rather than trust.

`crosscredit.vercel.app` · `github.com/OoJae/crosscredit`

BUIDL CTC 2026 Fall · live on Creditcoin CC3 testnet

THE PROBLEM

Credit history does not travel.

A wallet with years of Aave repayments on Ethereum arrives on every other chain as a stranger — and posts **\$1,500** to borrow **\$1,000**.

Not because the lender doubts that history. Because it cannot read that chain. Collateral stands in for information that already exists and is already provable.

The usual fixes swap evidence for a promise — a scorer's off-chain API, or unsecured lending on stated creditworthiness. Maple lost \$36M that way; Goldfinch wrote off ~\$18M.

150%

collateral demanded of a stranger — every chain restarts every borrower at zero

1.4B

adults outside formal credit systems — the population Creditcoin exists for

WHY NOW

Creditcoin can now verify foreign-chain facts in-contract.

The Attestcoin Protocol (USC) puts a block-prover precompile inside the Creditcoin EVM: a Merkle inclusion proof says the transaction is in the block, a continuity proof says the block is really on Ethereum, and the precompile checks both — synchronously, inside one CC3 block.

No oracle *we* run. No bridge holding funds. The attestor network is Creditcoin's own consensus, not our multisig.

THE FINDING THAT BECAME THE PROJECT

CC3 attests **Ethereum mainnet** as chainKey **3**, beside Sepolia's 1 — we found it in neither the docs nor the examples.

So the evidence can be real: unaffiliated Aave V3 history from a protocol whose capital was genuinely at risk — not events we issued to ourselves.

THE PRODUCT

Import history. Strike a tier. Borrow against it.

CHANGE BORROWER

Dashboard

Import History

Borrow

TERMS BY TIER

Priced from verified cross-chain history — not from a credit bureau, and not self-reported.

TIER	COLLATERAL	APR	MAX LOAN
Bronze	150%	14%	100 tUSD
Silver	130%	11%	500 tUSD
Gold	110%	8%	2,000 tUSD
Platinum (you)	85% UNCOLLATERALIZED	6%	10,000 tUSD

Platinum requires a score of 700 and zero late repayments. It is the only tier that lends more than the borrower posts, so a spotless record — not just a high score — is the condition.

BORROW

Collateral is native tCTC.

BORROW (tUSD)

100

Your tier

PLATINUM

Collateral needed

85 tCTC

Saved vs Bronze

65 tCTC

You are borrowing more than you post — 85 tCTC for 100 tUSD. That is only possible because you repaid \$90,145.248 of a new third party's capital on Ethereum, and that repayment was proven here rather than claimed.

Testnet deployment, real market data. History is proven from Ethereum mainnet and Sapida to Creditcoin (CC3) by the Atomico Protocol's native block proven precompile — a Merkle inclusion proof plus a chain-continuity proof, verified inside a single Creditcoin block. There is no oracle we run, no multi-sig we control and no bridge holding funds. Creditcoin's attester set is in the trust path, which is to say this needs no trust beyond the chain you are already setting on.

/explorer — five proven Aave repayments, score 800, no wallet needed

A valid proof of the wrong thing is worthless.

PRIMITIVE

HOW WE USE IT

<code>verifyAndEmit · single</code>	main ingest, via vendored USCBase (pinned @4ff9a3bf)
<code>verifyAndEmit · batch</code>	≤10 proofs on one shared continuity proof — no example exercises it. Ceiling confirmed at the precompile: 10 verifies, 11 reverts
<code>verify · read-only</code>	free pre-flight: <code>previewIngest</code> names the failing guard before any signature; <code>dryRunBatch staticCalls</code> a whole batch
<code>calculateTxIndex</code>	replay id — <code>keccak(chainKey, height, txIndex)</code>
<code>EvmV1Decoder</code>	external library, <code>delegatecall</code> — so we deploy our own build
<code>ChainInfo 0x...0fd3</code>	<code>getSupportedChains</code> , attested heights

FIVE CHECKS AFTER EVERY PROOF

- 1 replay — `queryId` guard, exercised live
- 2 source auth on the `(chainKey, emitter)` pair — mainnet spoofing is otherwise free
- 3 `receiptStatus == 1`, decoded in-contract — the precompile does not check success
- 4 dispatch on the log's own emitter, never the caller's action byte
- 5 `topic0` must match the source's registered signatures

MEASURED, ON CHAIN

Every number is live on testnet.

134,167

gas per event — nine Sepolia proofs in one CC3 tx (0xffad0a92...), vs 532,140 one at a time

0 → 800

five real Aave V3 mainnet repayments, proven and scored to Platinum

9:39

end to end, measured — ~8.5 min Sepolia attestation, ~15 s verification in one CC3 block

850 vs 1,300

collateral for 1,000 tUSD: proven history against a self-dealt wallet — same pool, same free view call

5/5

attacks rejected live — 3 by the precompile, 2 by the registry. npm run negative-paths, no wallet needed

10 | 11

batch ceiling probed at the precompile itself: ten verifies, an eleventh reverts — artifact committed

Creditcoin's own mission, made cross-chain.

Creditcoin exists to put credit history on-chain for borrowers the formal system cannot see — years of real lending records across Africa and Southeast Asia prove the model.

CrossCredit generalises it: reputation earned *anywhere* becomes collateral-relief *here*. The score is computed inside the EVM that verified the evidence — deterministic, eight constants, no owner-tunable weights, no off-chain model.

- Every comparable scorer — Spectral, Cred, Nomis, RociFi — computes off-chain and delivers a number by API
- Undercollateralized DeFi keeps failing on *stated* creditworthiness; nobody prices on *proven* repayment
- Credit-data network effects: every proven repayment makes the registry more valuable to the next lender

BUSINESS MODEL

Lenders pay for information. Borrowers pay less for capital.

REVENUE	MECHANISM
Origination fee	basis points on every loan the registry prices
Rate spread	tier-priced lending pool — Platinum at 85% collateral is the acquisition hook
Registry reads	third-party pools querying scoreOf / demonstratedCapacity for their own terms

BRONZE
150%

SILVER
130%

GOLD
110%

PLATINUM
85%

The tier sets the rate. The credit line above collateral is capped by the largest single repayment *proven* to a real third-party protocol.

The threat model is the backlog.

- **Close multi-block wash lending** — duration-of-exposure scoring; the same-transaction flash-loan path is already closed and tested
- **More source chains** as CC3 attests them — the registry authenticates on (chainKey, emitter), so a new chain is a registration, not a rewrite
- **Mainnet import in the app** — today the flagship path is CLI (prove:mainnet); it belongs in the Import tab
- **Credit delegation** — proven capacity as a primitive other pools consume
- **RWA pools** — Creditcoin's real-world lenders pricing on imported reputation
- **Audit** — CertiK credits from this prize, pointed first at the ingest path

Twelve open items are disclosed in docs/THREAT_MODEL.md — what is unsolved is written down next to what is.

THE ASK

Solo build, 23 days, live end to end. Ready for CEIP.

Built from Aug 13 for BUIDL CTC 2026 Fall — contracts, worker, frontend, film and this deck by one builder. Everything user-facing runs against the real precompile on live CC3; nothing in the demo path is mocked.

The ask: **CEIP fast-track** — funding the audit and the first external lending pool on Creditcoin mainnet.
